Last time we examined how to program the [STM8s microcontroller using the Arduino IDE](#). This way may work for developers who are familiar with the Arduino IDE and want to build quickly, and professional projects, but there are more ways to get the same result. Thus for today's tutorial, we are going to examine how to use traditional tools like the [Cosmic C compiler](#) along with [STVD](#) to program the [STM8s](#) microcontrollers.

There are several members of the STM8s microcontroller out there but for this tutorial, we will work with the [STM8S103F3P6](#) microcontroller which is the cheapest, and most popular member of the family. The popularity of the [STM8S103F3P6](#) makes it a perfect microcontroller for beginners as you find support for it across several forums on the internet.

For easy prototyping, we will use the STM8sBlue development board which is essentially a breakout board for the [STM8S103F3P6 MCU](#) with a USB interface, breadboard compatibility, and a few other components to facilitate the development of prototypes for projects based on the MCU.

In addition to the STM8sBlue development board, we will need the [ST-LINK programmer](#), preferably the [ST-LINK v2](#) programmer. It will be used to upload firmware from the PC to the microcontroller.

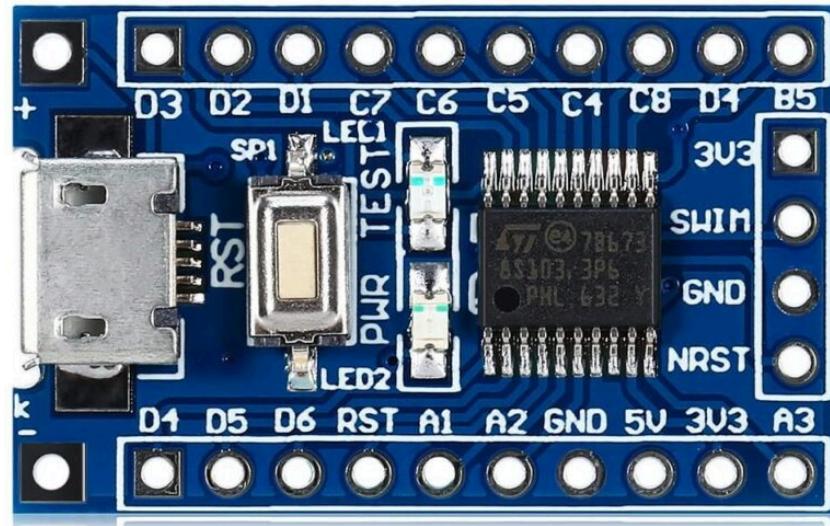

Our goals for today's tutorial will be to examine how to set up the tools, and for a demo, we will flash the microcontroller with the hardware hell LED blink example.

Ready? Let's go

REQUIRED COMPONENTS

The components required to replicate and follow this project includes:

1. [STM8sBlue development board](#)
2. [ST-LINK v2 programmer](#)
3. Jumper Wires
4. Breadboard
5. 220 ohms Resistor
6. LED

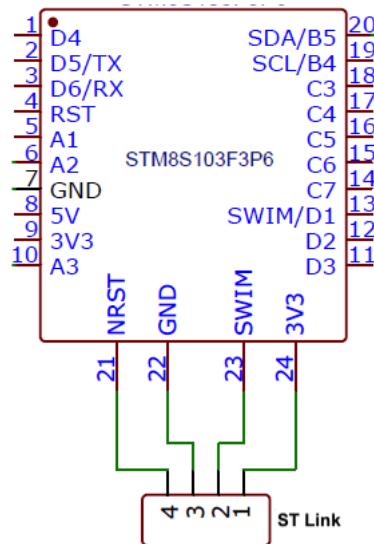

STM8s Blue

The [STM8sBlue](#) and the [ST-Link programmer](#) can be bought from the attached links, while others can be easily obtained from your favorite electronics component store. The resistor and LED are only important if you will prefer to use an LED other than the one onboard the STM8sBlue.

SCHEMATICS

Aside from schematics for folks who will not be using the onboard LED, the only schematics associated with this project is for the connection between the STM8Sblue and the ST-Link V2 programmer. Connect both of them as shown in the schematics below:

Schematics

A pin-pin map showing how the **ST-Link V2** is connected to the dev board is also provided below to make the connection easy to follow.

ST-Link V2 -STM8S103F3

1(3.3v) - 3v3
 2(SWIM) - SWIM
 3(GND) - GND
 4(RST) - NRST

With this done, we can now proceed to set up the software side of the project.

INSTALL THE COSMIC C COMPILER AND STVD

To program the microcontroller, we need an IDE and a compiler. As mentioned during the introduction, we will use the **Cosmic C compiler** and the **ST Develop** (STVD) IDE. Unfortunately, both software is only available in the Windows OS version so you will need a windows based machine or a partition install and use them.

Head over to [Cosmic and ST websites](#) and download the software. Both software is free to use and will only require you to sign up on the websites to download.

With both software downloaded, run the installation, following the on-screen instructions displayed by the setup wizard. The STVD IDE should install fuss, but the Cosmic C compiler will request that you get a **free license key**, with a prompt that asks for your email address.

The prompt is displayed after a readme file that contains guidelines on use, is closed.

Cosmic STM8 Compiler Free Special Edition Registration X

```

User * :

Company * :

E-mail * :

License request

* : required.

Fill the information requested by the prompt, select the “**On the Web**” option (if you are connected to the internet), and click on done. This should lead you to a webpage where you will be required to enter your email address again if not auto-filled. With these complete, you should get a license request process notification, and receive the license key in your email, a few minutes after submitting the request. Due to spam algorithms, the license email may be “quarantined” in the spam section of your email box. Make sure also to check there.

Emmanuel Odunlade,

Thank you for using Cosmic Products.

According to your request, please find attached the free license that will allow you to use the STM8 and STM32 (limited) compilers for 1 year.

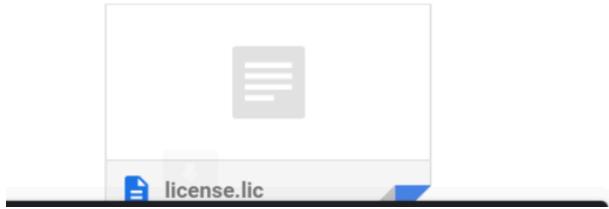

This file must be copied into the "license" sub-folder of the compiler installation folder.

Support is provided via:

- support.stm8.free@cosmic.fr or
- the STM8 discussion forum on ST Community website

Regards,

The Cosmic Software Team.

With the license file received, follow the installation instruction, and copy the **license.lic** file to the "license" sub-folder of the COSMIC installation folder on your computer. In my case the license sub-folder was located at this path: "**C:\Program Files (x86)\COSMIC\FSE_Compilers\CXSTM8\License**".

With this done, both software should now be fully installed and ready for use.

One other thing we need, that is probably better to also get at this stage, is the **Standard Peripheral Library** for the **STM8S103F3P6** microcontroller. This library can be downloaded from ST's website, but for simplicity and ease of use, this nicely modified library by [Circuit Digest's Aswirth Raj](#) might be a good choice.

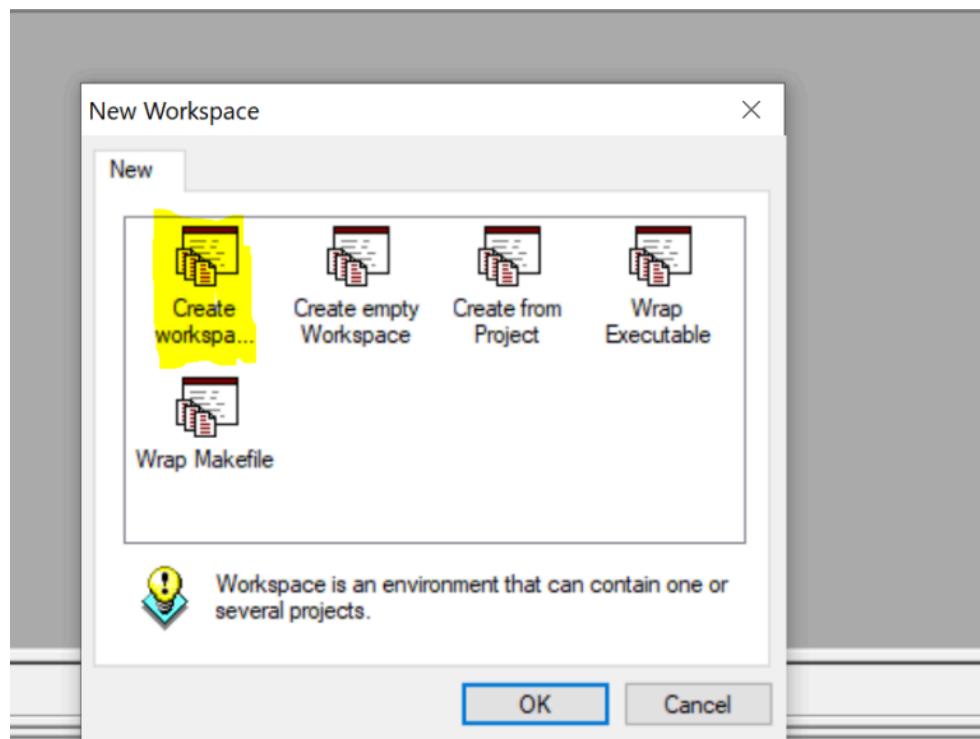

With all these in place, we can now proceed to use these tools to develop the code for our project.

CODE

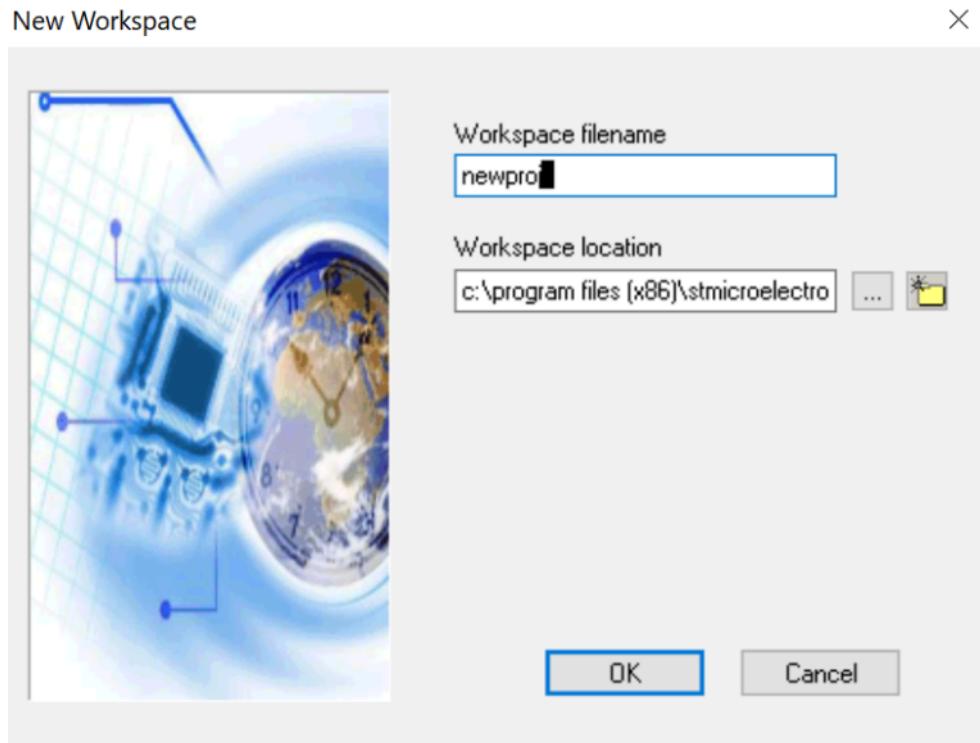

To write the firmware, we need to create a new project specifying the microcontroller for which the firmware is to be developed and the destination where all project files will be stored. Follow the steps below to do this:

Start by opening STVD and select **File -> WorkSpace**, in the pop-up, select "**New Workspace**" and enter the Project name and path where the program will be saved. I am naming my program BareMinimum and saving it in a folder on the desktop. Click OK and you will get the New Project dialog box as shown below.

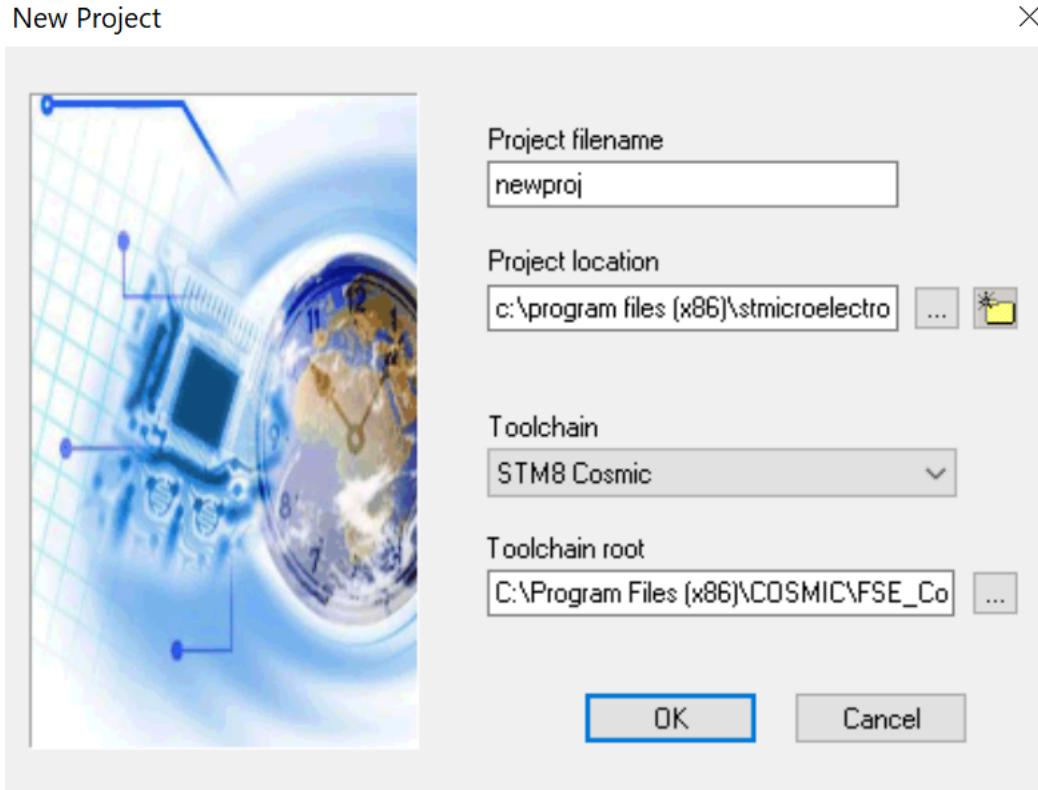

1. Open the Installed ST Visual Develop and go to **File -> "New Workspace"** to create a new workspace.
2. On the resulting pop-up box, select the "**Create a Workspace and Project**" option highlighted in the image below.

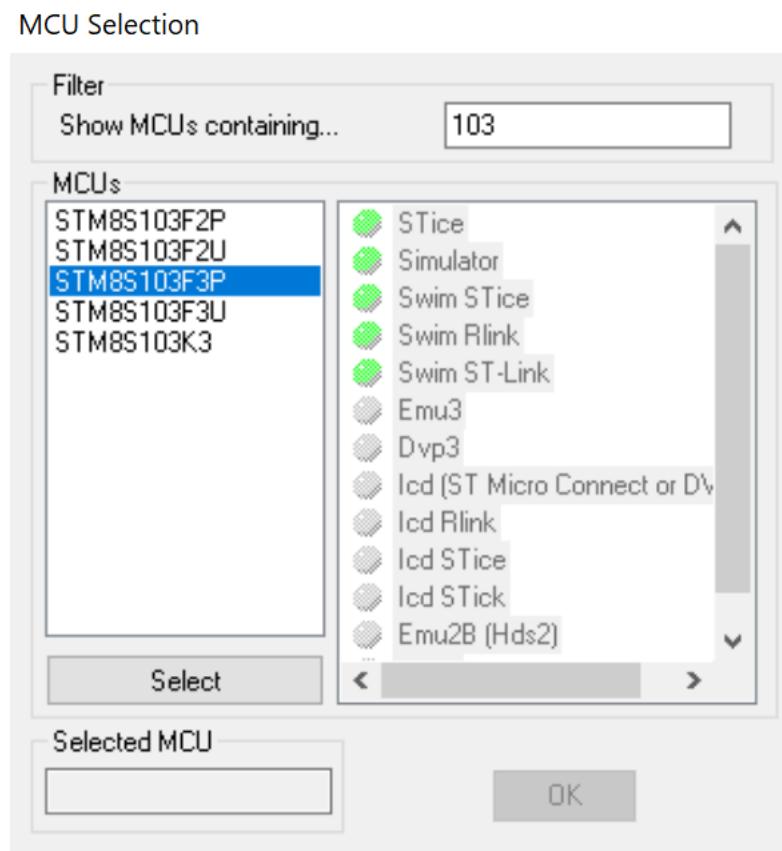

3. On the next window, enter your preferred workspace name. I will be calling this “**newproj**” and will save it in the default location. Click OK when done.

4. The next window will require you to provide a project filename, preferred storage location, the toolchain to be used, and the root address to the toolchain. For me, the project name will be **newproj**, and the directory will be the default. We will use the Cosmic C compiler so you should set the toolchain as **Cosmic** and the toolchain root should be the path where your Cosmic compiler was installed. The default path address is "**C:\Program Files (x86)\COSMIC\FSE_Compilers\CXSTM8**" and should also be the path on your machine if it was not changed during installation. You can also use the **...** button to navigate to the CXSTM8 folder.

5. After clicking OK above, the MCU selection window will come up. Fill as shown in the image below, selecting the **STM8S103F3P** microcontroller.

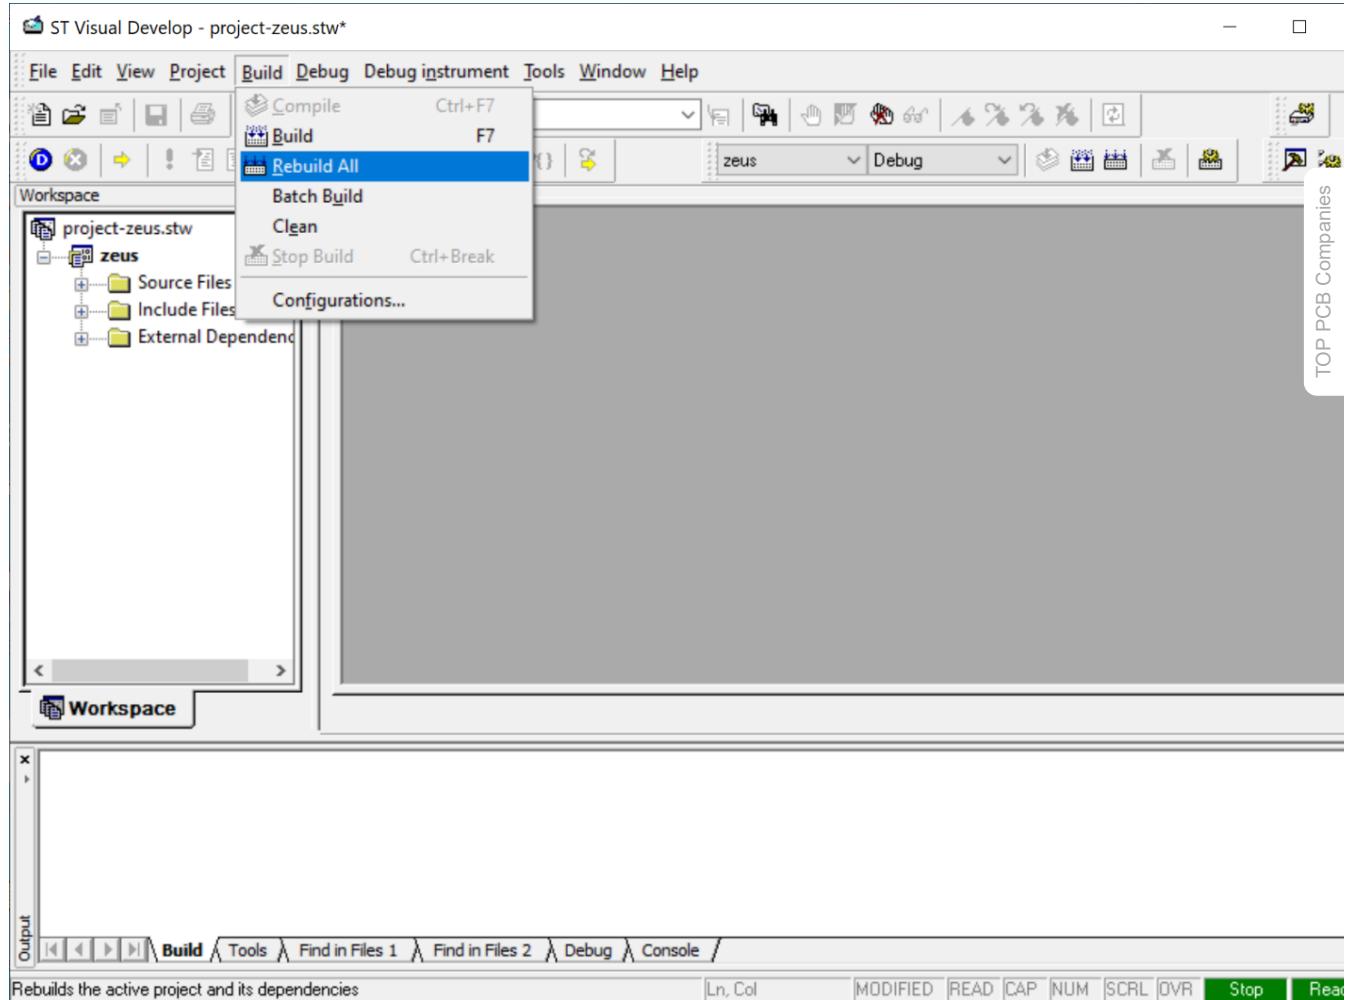

You can quickly search for the microcontroller by typing its name in the search bar. With this done, click OK. You should now be able to see the STVD workspace.

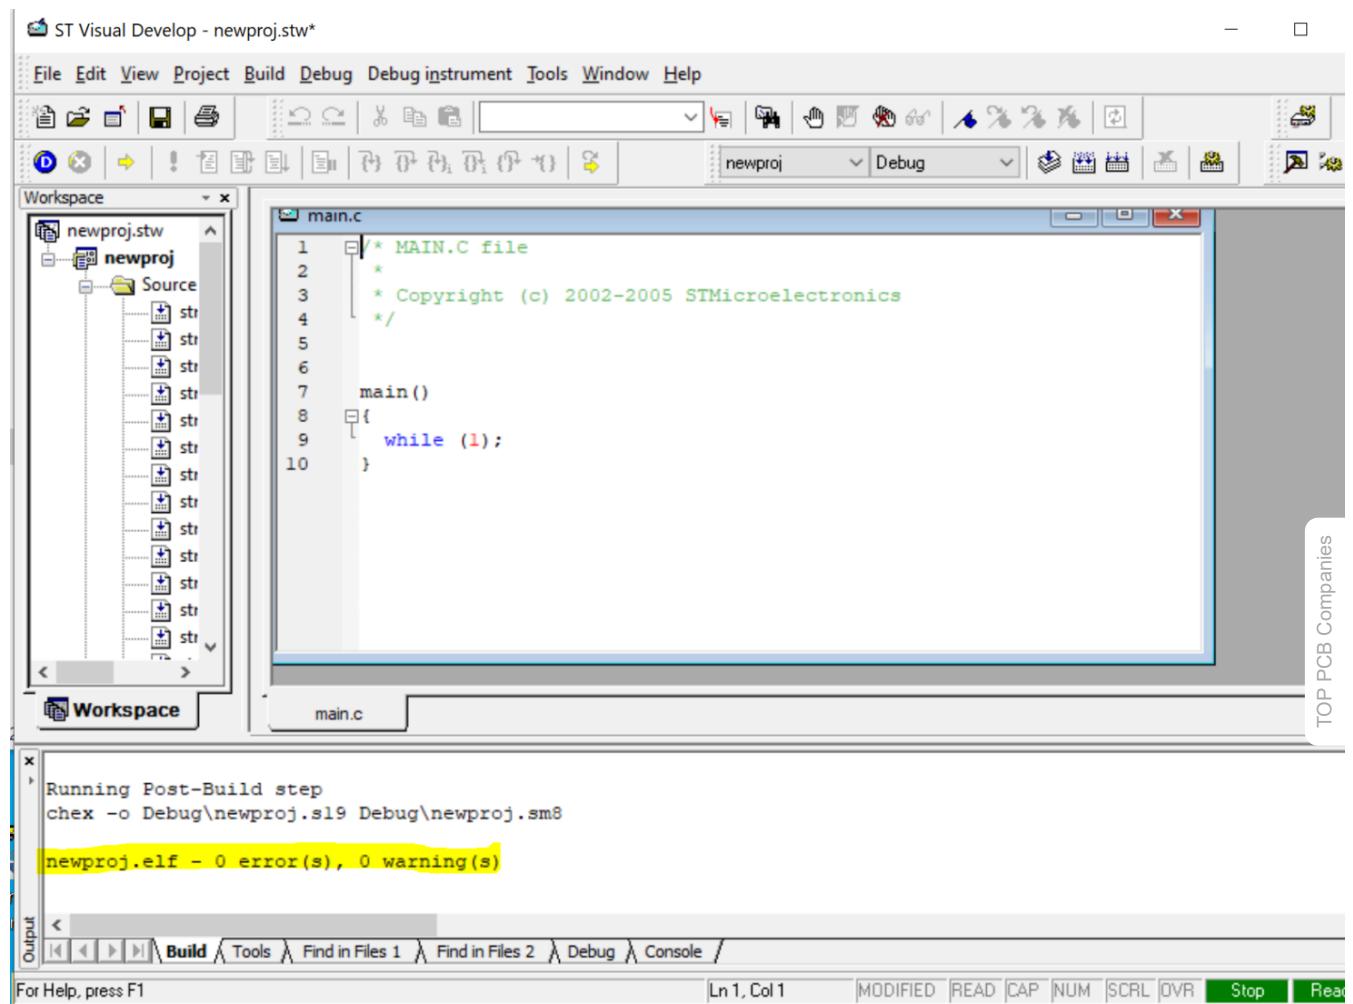

6. Next, we need to add the SPL libraries we downloaded to the project files. To do this, expand the project folder (**newproj**) in the workspace, right-click the “**Source files**” folder and click on the “**add files to folder**” option and navigate to the “**src**” folder in the library we downloaded. select all the “**.c**” folder and add them.

7. Next, we need to also add the header files. Right-click on the “**include files**” folder on the workspace, and select “**Add files to folder**”. Navigate to folder of the library we downloaded and add all the “**.h**” files.

8. Verify library addition and general setup by building. Click on the “**build**” button and select “**rebuild all**” followed by the “**compile**” button.

If the build is successful, you should see “**zero build errors**” displayed on the command line like in the image below.

TOP PCB Companies

With this done you are now ready to start writing the code for our project.

As mentioned earlier, the code for today's project will be to blink the onboard LED at certain intervals. As with all our projects, I will do a brief explain the code and provide the complete code at the end.

The code will be written in the **main.c** file which is automatically generated when you create a new project. We start the code by including the STM8 which helps adds some level of code **IntelliSense** to our project.

```
1. #include "STM8S.h"
```

Next, we write the delay function. Unlike with the Arduino where the functions are pre-written and we just call them to use, here you have to write n functions your self. The delay function will be used to indicate how long the led stays in a particular state before switching to the other state.

```
1. void delay (int ms) //create delay function
2. {
3. int i =0 ;
4. int j=0;
5. for (i=0; i<=ms; i++)
6. {
7. for (j=0; j<120; j++) // Nop = Fosc/4
8. _asm("nop"); //Perform no operation //assembly code <span style="white-space:pre"> </span>
9. }
10. }
```

Next, we write the main function. We start by deinitializing Port B, i.e., the port to which the pin of the onboard led is associated. While deinitializing not mandatory, it helps totally free up the port from whatever function it was used for before, ensuring your project is hitch-free.

```
1. main()
2. {
```

```
3.   GPIO_DeInit(GPIOB); // deinitialize port B
```

Next, we declare the pin to which the onboard led is connected as a push-pull output pin with default low status.

```
1.   GPIO_Init (GPIOB, GPIO_PIN_5, GPIO_MODE_OUT_PP_LOW_SLOW); //Declare PB5 as a default low push-pull output pin
```

Finally, we write the **while loop** function. Here we basically place the code to turn ON and OFF the onboard led. For this, we will use the **GPIO_Write** function which reverses the state of the pin. So if it was on before, it turns it OFF, and vice versa. We will also add a delay of **200ms** to allow us to see without the eye's persistence effect.

```
1.   while (1)
2.   {
3.     GPIO_WriteReverse(GPIOB,GPIO_PIN_5);
4.     delay (200);
5.   }
```

The complete code for the project is provided below;

```
1.  /* MAIN.C file
2.  *
3.  * Copyright (c) 2002-2005 STMicroelectronics
4.  */
5.
6. #include "STM8S.h"
7.
8. void delay (int ms) //create delay function
9. {
10.   int i =0 ;
11.   int j=0;
12.   for (i=0; i<=ms; i++)
13.   {
14.     for (j=0; j<120; j++) // Nop = Fosc/4
15.       _asm("nop"); // just an assembly code.
16.   }
17. }
18.
19. main()
20. {
21.   GPIO_DeInit(GPIOB); // deinitialize port B
22.
23.   GPIO_Init (GPIOB, GPIO_PIN_5, GPIO_MODE_OUT_PP_LOW_SLOW);
24.   //Declare PB5 as a default low push-pull output pin
25.
26.   while (1);
27.   {
28.     GPIO_WriteReverse(GPIOB,GPIO_PIN_5);
29.     delay (100);
30.   }
31. }
```

UPLOADING THE CODE

With the code complete, its time to hook up your board to your computer and upload the code. The process of uploading code to the board is not as forward as with the Arduino IDE but its easy to follow and should become seamless once you get the hang of it.

Once the code is complete, click on the **Build -> rebuild all** and ensure there are no errors. If everything is fine, it should return the "**0 errors and 0**" line. With this done, hit the **Compile** button. If there are no errors, the program should compile easily and you should see the "**0 errors and 0 warnings**" compile success line.

The screenshot shows the ST Visual Develop interface. The top menu bar includes File, Edit, View, Project, Build, Debug, Debug instrument, Tools, Window, and Help. The toolbar below has various icons for file operations. The left sidebar is the Workspace, showing a project named 'newproj' with a 'Source' folder containing multiple 'str' files. The main editor window displays 'main.c' with the following code:

```

3  * Copyright (c) 2002-2005 STMicroelectronics
4  */
5
6 #include "STM8S.h"
7
8 void delay (int ms) //create delay function
9 {
10     int i =0 ;
11     int j=0;
12     for (i=0; i<=ms; i++)
13     {
14         for (j=0; j<120; j++) // Nop = Fosc/4
15             _asm("nop"); // just an assembly code.
16     }
17 }
18
19 main()

```

The bottom output window shows the compilation process:

```

Compiling main.c...
cxstm8 -i"..\..\..\..\users\emmanuel\odunlade\desktop\stm8s103f3_spl-master\inc" -i"..\..\..\..\users\emmanuel\odunlade\desktop\stm8s103f3_spl-master\src" main.c:
main.o - 0 error(s), 0 warning(s)

```

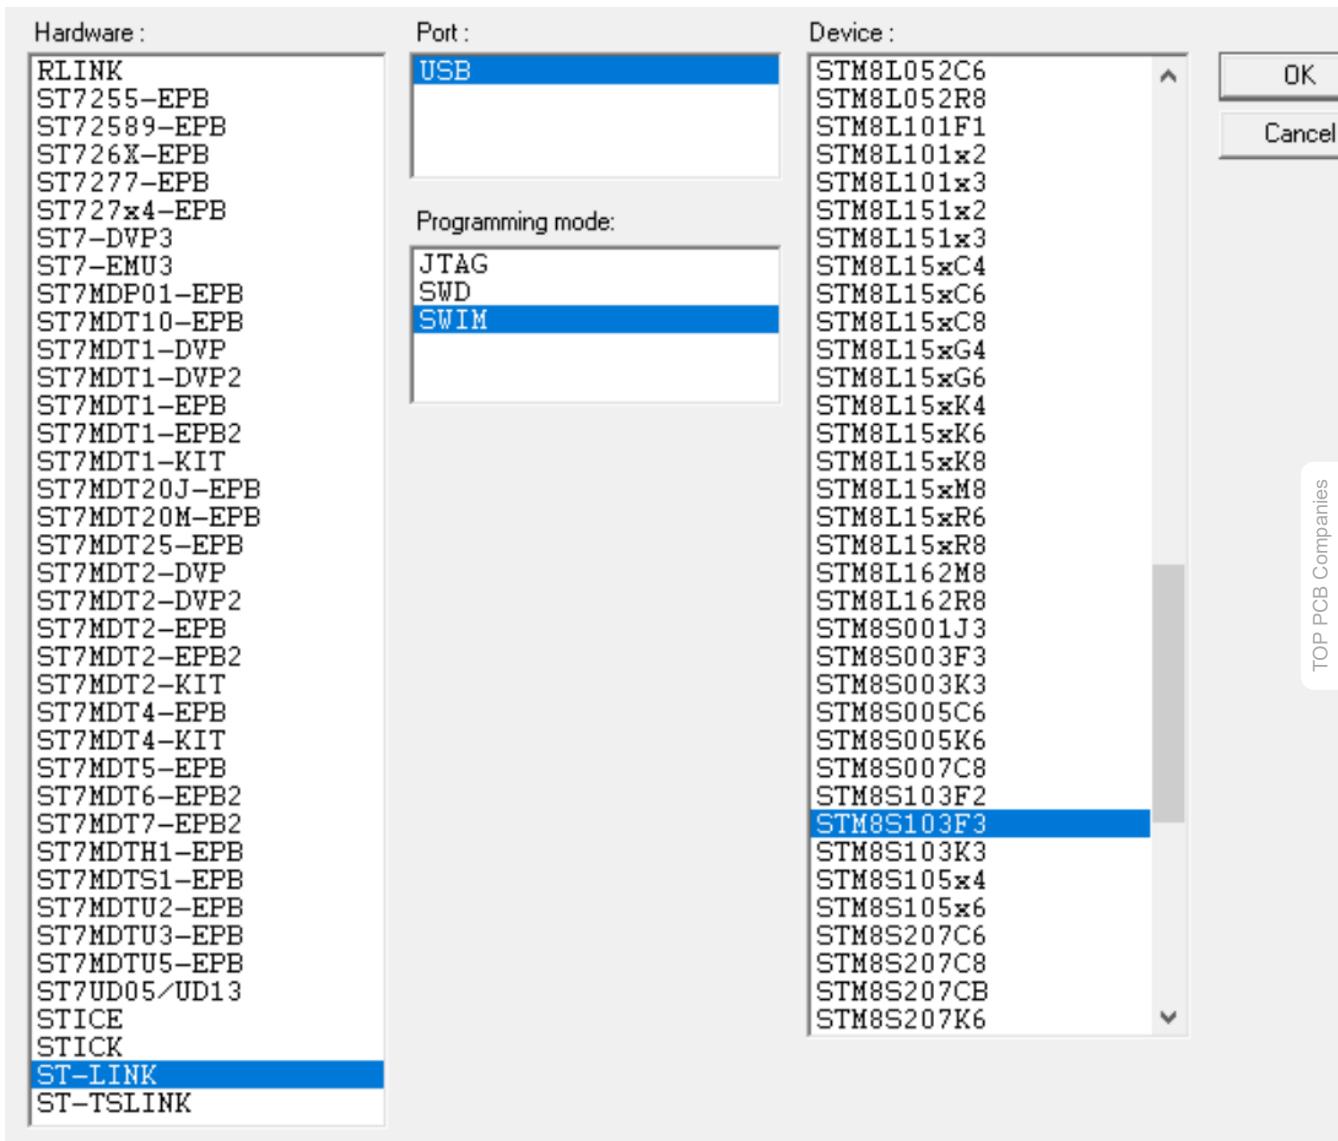

The status bar at the bottom indicates Ln 10, Col 13, MODIFIED, READ, CAP, NUM, SCRL, OVR, Stop, and Read.

TOP PCB Companies

With the successful compiling, a ".s19" file will be generated under the debug directory of the project's folder. This file is similar to the **Hex** file and it you will upload to the microcontroller. To upload the .s19 file to the microcontroller we will use the **ST Visual Programmer (STVP)** which would have installed alongside STVD.

When opened, the STVP presents the configuration page shown below. Select the programmer, the programming mode, and the device/microcontroller in this case are **ST-Link**, **SWIM**, and **STM8s103F3** respectively.

Configuration

TOP PCB Companies

Hit the OK button when complete. This should launch the STVP interface.

Click on “**file->Open**” and navigate to the debug folder where you have the **.s19** file we generated earlier and open it. Click on “**Program**” and select **Tab**. These should begin the flashing process and the firmware should now be loaded on your microcontroller. If successful, you should see the following command prompt area of the software:

```
< File successfully loaded. File Checksum 0x5FD6
> Programming PROGRAM MEMORY area...
Cut Version and Revision of device: 1.2
< PROGRAM MEMORY programming completed.
> Verifying PROGRAM MEMORY area...
Cut Version and Revision of device: 1.2
< PROGRAM MEMORY successfully verified
```

and the LED on the STM8sblue should also start blinking at a pace equal to the 200ms we specified.

It is probably important to note that before launching the STVP, you should connect the microcontroller via the ST-link to your computer. If you are using ST-Link for the first time, the device driver will automatically be installed on your PC. If this is not the case you might need to run a quick google search to find out the requirements for your computer.

That's it, folks! There you have it. If you have any challenges with any part of the project, do reach out to me via the comment section. I will be happy to help!

Thank you very much for this clear and understandable education. I can say that it was very useful for me. I wish you success in your work.
